ACKNOWLEDGEMENT

Upon completion of this project, I would like to express my gratitude to many parties. My heartfelt thanks goes to my supervisor, Dr. Famiza Abdul Latif for her continuous guidance and assistance as well as for her time in helping me and for her encouragement. I also wish to convey my special thanks to my parents and family members who have been supporting and believing in me in everything I do and for always being there for me. My appreciation also goes to Mr. Mohd Khairul Tajudin and other lab assistants in Faculty of Applied Sciences for their helping hand in getting my laboratory works done in time as well as for their assistance in using the equipments and for the access of chemicals in the laboratory. I would also like to thank my friends and fellow classmates especially, Norashima Kamaluddin for being with me through thick and thin and for their unforgettable help and warm support throughout my research work. Last but not least, I would like to thank every single person for their contributions either directly or indirectly in helping me completing this thesis.

ABSTRACT

THE EFFECT OF SALT CONCENTRATION IN FILLER MODIFIED PMMA/ENR 50/LiCF₃SO₃ ELECTROLYTE

A freestanding film was obtained from poly(methylmetacrylate), PMMA/50% epoxidised natural rubber, ENR 50 blend by casting method. It was found that the addition of 0.1 g of SiO₂ filler improved the dispersion of ENR 50 in the blend system. This has been confirmed from its optical micrograph. The addition of filler also increased the amount of salt that could be dissolved in the PMMA blend. It was found that the maximum amount of salt that can be accommodated into the system was 0.3 g. Blend containing this amount of salt exhibited the highest ionic conductivity of 10⁻⁷ S cm⁻¹ at room temperature. From its optical micrograph, it showed the most smooth surface which assist the transportation of lithium ion in the polymer blend matrix. It also showed the highest intensity of $\nu(\text{SO}_3)$ band indicating the presence highest number of free triflate anion. When more than 0.3 g of salt was added into the blend, the overall system became congested with excessive lithium salt which reduced the ionic conductivity of the system.

CHAPTER 1

INTRODUCTION

1.1 Polymer electrolytes background

To date, liquid-based electrolytes batteries are still the main choices because they exhibit high energy density and longer charge retention characteristics. However, problems related to leakage of toxic liquid electrolytes and incompatibility with the lithium metal anodes still remain unsolved. To overcome these problems, solid electrolytes are the alternative. They exhibit several advantages over liquid electrolytes, such as no more leakage of toxic electrolytes and can be widely used in electrochemical power devices and power source (Zhou and Fang, 2007).

There are many types of solid electrolyte systems, including solid crystalline electrolytes, glass electrolytes, and polymeric electrolytes. Amongst them, polymer electrolytes had received much attention due to its ability to be fabricated into thin flexible film, has a wide range of electrical properties and good mechanical strength (Ahmad, 2009). Polymer electrolytes can be defined
