ACKNOWLEDGEMENT

Alhamdulillah praise is to ALLAH S.W.T for giving me good health and strength to complete this final year project. I would like to express my deepest gratitude to my supervisor, En. Mohd Abdul Fatah B. Abdul Manan and my co-supervisor, Cik Shadatul Hanum Bt Rashid for giving me knowledge, advices and moral support. Only Allah S.W.T can pay for your kindness.

I would like to say thank you to our laboratory assistants, En. Adnan B. Ismail and En. Khairul B. Mohd Tajudin who gave a lot of help when I need it. Special thanks to Cik Fatimatuzahraa Bt. Mohd Fadzal for carrying out the Carbon, Hydrogen, Nitrogen (CHN) analysis.

Most important, I would like to thank my parents, En. Arifin B. Daud and [redacted] who were always there for me and supported me to complete this project. Also my friends who gave a lot of cooperation. Finally, I wish to thank everyone that help me to complete my project successfully.

Nurul Amalina Arifin

ABSTRACT

SYNTHESIS, CHARACTERIZATION, AND ANTIBACTERIAL ACTIVITY OF Cu(II) AND Ni(II) TRANSITION METAL COMPLEXES OF NOS TRIDENTATE SCHIFF BASE DERIVED FROM *S*-2-FLUOROBENZYL DITHIOCARBAZATE WITH 5-CHLOROISATIN

A Schiff base ligand, *S*-2-fluorobenzyl 2-(5-chloro-2-oxoindolin-3-ylidene)hydrazinecarbodithioate was synthesized *via* the condensation reaction between *S*-2-fluorobenzyl dithiocarbazate and 5-chloroisatin. The Schiff base was reacted with Cu(II) and Ni(II) metal salts to produce metal complexes. The Schiff base and its metal complexes were characterized by elemental analysis and various physico-chemical techniques. The ligand was capable of being a versatile chelating ligand. It acted as a uninegatively charged bidentate ligand when it was bonded to Cu(II) ion via the azomethine nitrogen and thiolate sulfur. In the Ni(II) complex, it acted as a uninegatively charged tridentate ligand when it was bonded to the metal ion through carbonylic oxygen. Square planar geometry was assigned to the Cu(II) complex and Ni(II) complex exhibit the tetrahedral geometry. Antibacterial screening was done on the Schiff base ligand and its metal complexes. Cu(II) complex showed that it was moderately active against the Gram positive bacteria strain and Cu(II) complex also showed lower activity against the Gram negative bacteria strain. Both Schiff base ligand and Ni(II) complex showed no activity against the Gram negative bacterial strain.

CHAPTER 1

INTRODUCTION

1.1 Schiff bases

Schiff bases are compounds that contain azomethine group (-C=N-) in their structures. They can form stable complexes with transition metals and they can act as bi- or tri-dentate ligands. Schiff base ligands can be formed from the condensation reaction between different types of amines and carbonyl compounds (aldehyde or ketone) (Imran *et al.*, 2006).

Basically, ligands are anions or neutral molecules possessing lone pair(s) of electrons and can act as Lewis bases. The formation of a complex ion involves the donation of a pair of electrons from the ligand to the empty orbitals of the central metal atom or ion. Many ligands are described as monodentate or one-toothed as they 'bite' the metal at one place. There are also numbers of ligands described as tetradentate, hexadentate, and polydentate (Rajavel *et al.*, 2008).

Transition metal complexes having oxygen and nitrogen donor Schiff base possess unusual configuration, structural liability and sensitive toward molecular environment. The environment around the metal centre "as coordination geometry, number of coordinated ligands and their donor group" are the key factors for metalloproteins to carry out specific physiological functions (Golcu *et al.*, 2005).
