MATHEMATICAL MODELING OF BRAIN TUMOR CELL GROWTH FOR PASSIVE, ACTIVE AND OXYGEN TRANSPORT MECHANISM WITH MICROGRAVITY CONDITION

NORFARIZAN BINTI MOHD SAID

Thesis submitted in fulfillment of the requirements for the degree of **Doctor of Philosophy of Science**

Faculty of Computer and Mathematical Sciences

April 2018

ABSTRACT

The unpredictable conduct of the brain tumor cells present difficulties in creating precise models. The limitation of medical imaging in forecasting the nature of the tumor growth and the costly techniques for diagnostic and treatment posed an obstacle to the effort in understanding and fighting this life-threatening disease. As the tumor itself can only be detected and treated through the biological process, a good mathematical model should represent the important biological aspects with useful solution that contribute to further understanding of the problem. Addressing the current challenges in developing a realistic model by bridging the theoretical with the clinical applications, this research aims to govern mathematical models for brain tumor cell growth by emphasizing the cell migration and proliferation as the key characteristics. The models of passive and active cell mechanisms are representing the tumor cell migration while the model of oxygen transport mechanism configures the cell proliferation. New parameters for oxygen and gravity effects are included as the model novelty. The conditions of microgravity and oxygen deprivation are presented using the microscopic model of the tumor cellular dynamics. The models developed are in the form of parabolic equations which is discretized using the Finite Difference Method (FDM) with weighted average approximation. Numerical iterative methods, namely Jacobi (JAC), Red-Black Gauss-Seidel (RBGS), Red-Black Successive Over Relaxation (RBSOR) and Alternating Group Explicit (AGE) method are used to solve the discretized models. The sequential algorithms for these methods are developed and written in Matlab R2009a code to produce the numerical simulations of the models. Magnetic Resonance Imaging (MRI) images of a specific brain tumor patient are obtained from the local hospital for validation purposes. The image processing technique known as Enhanced Distance Active Contour (EDAC) are utilized in edge detection of the MRI images to get the parameter estimations for comparison with the model simulations. Simulations for one and two-dimensional space for all models are performed and discussed. Numerical results presented include the computational complexity of the iterative methods. The research found that the passive cell mechanism model is appropriate to describe the early stage of the tumor growth while the active cell migration model is good to describe the invasive tumor stage. It is also noted that oxygen and gravity condition play a big role on the tumor cell growth which could also controlled their internal cellular dynamics. The research proposed that the models can be used for brain tumor growth prediction, visualization, observation and monitoring purposes. The two-dimensional model provided a better visualization of the tumor since it provides information on diffusion and velocities in multiple directions at each grid point at each computational interval. The computation of velocity profiles in two dimensions allows the accurate representation of tumor cell growth and better prediction of the effects of oxygen deprivation and microgravity conditions.

ACKNOWLEDGEMENT

Thank You Allah for giving me the opportunity to embark on my PhD and for completing this long and challenging journey successfully. My gratitude and thanks go to my supervisors, Prof. Dr. Hjh. Arsmah Ibrahim and Dr. Fatimah Yahya. Thank you for the support and patience in assisting me with this project. Special thanks to my co-supervisor, Assoc. Prof. Dr. Hjh. Norma Alias for the great ideas as well as for the continuous moral support throughout the years.

My appreciation goes to En. Johari from the Hospital Universiti Sains Malaysia (HUSM), Kubang Kerian for the help with the MRI data acquisitions and all my friends in Universiti Teknologi MARA (UiTM), Universiti Teknologi Malaysia (UTM) and Agensi Nuklear Malaysia (NM) who are always available for sharing knowledge and experiences throughout this journey. My indebtedness to Pn. Badariah from Fakulti Sains Komputer dan Matematik (FSKM), UiTM for her sincere help and concern for me and my study.

Finally, this thesis is dedicated to my parents for the vision and determination to educate me and my parents in law for their understanding and support. It is a special remembrance of my late father and father in law that passed away while I am still struggling in the last part of the journey. It is true when people say that PhD is not just an academic scroll but a life journey to survive. It takes a lot of bravery to face your own personalized set of fears, exhaustive emotionally throughout the journey. This piece of victory is mostly dedicated to my beloved husband, Mohd Hafizi Borhan and children, Muhammad Mirza Wildan and Nur Wijdan Safiyya. Thank you very much for your love and sacrifice.

May Allah grant us all Jannatul Firdausi, insyaaAllah..aamiin.

CHAPTER ONE INTRODUCTION

1.1 RESEARCH BACKGROUND

Tumor and cancer are two frightening words representing a devastating disease that becomes a nightmare to people whom are diagnosed with it. These two terms are sometimes used synonymously and lead to misinterpretations especially in a discussion of possible cancer diagnosis. Therefore, a clear distinction between the two terms is worth to be highlighted. The word tumor can be defined as the uncontrolled new cells growth in body tissue which competes with normal cells for nutrients. Tumor that is also known as neoplasm is named based on the part of the body where the tumor first arises. There are many types of tumor which can either be a benign or malignant tumor. A benign tumor usually addressed as tumor, refers to the noncancerous tumor that is localized. The tumor is unlikely to spread to other parts of the body and well responsive to treatment. On the other hand, a malignant tumor called as cancer is a type of tumor that shows resistance to treatment, invades surrounding tissues and other parts of the body and often recurs after removal. In simple words, it can be said that not all tumors are cancers but all cancers are certainly tumors.

A benign tumor which is non-cancerous could probably lead to a serious disease if it is left untreated. However, a malignant tumor (cancer) is a particularly life-threatening type of tumor. The word cancer itself was taken from the Greek word 'karkinos' which describes the moving crab as it grabs onto something and will not let go. The history of cancer research reviewed by Weinstein and Case (2008), Sudhakar (2009) and Hajdu (2011) revealed the oldest description of cancer in the Edwin Smith Papyrus, discovered in Egypt back to about 3000 BC. It is a part of an ancient Egyptian textbook on trauma surgery. The signs and evidence of cancer are also found among fossilized bone and human mummies back then.

The ancient theory of cancer known as the humoral theory was introduced by Hippocrates in between 460 to 370 BC (Sudhakar, 2009; Weinstein & Case, 2008). In the theory, human body is said to contain four types of body fluids known as yellow bile, black bile, phlegm and blood as shown in Figure 1.1. Cancer was predicted to be
