ABSTRACT

Mobile cloud computing (MCC) technology possess features mitigating mobile limitations and enhancing cloud services. MCC application penetration testing issues are complex and unique which make the testing difficult for junior penetration testers. It is complex as MCC applications have three intersecting vulnerability domains, namely mobile, web, and cloud. The offloading process adds uniqueness and complexity to the MCC application penetration testing in terms of generating, selecting and executing test cases. To solve these issues, this thesis constructs a model for MCC application penetration testing that reduces the complexity, tackles the uniqueness and assists junior testers in conducting penetration tests on MCC applications more effectively and efficiently. The main objectives of this thesis are to discover the issues in conducting penetration testing on MCC applications and to construct and evaluate MCC application penetration testing model. Design science research methodology is applied with four phases: (i) Theoretical framework construction phase (ii) Model construction phase entails designing the components and processes of MCC application penetration to reduce the complexity and address offloading; (iii) Model implementation phase implements the components and processes of the model into model guidelines and integrated tool called PT2-MCC. This tool manages the repositories, generates and selects test cases, and implements the mobile agent component; (iv) Model evaluation phase applies case study approach and uses an evaluation framework to evaluate the model against selected testing quality and performance attributes. In model evaluation phase, a junior penetration tester conducted two case studies on two MCC applications built by extending two open source native mobile applications. The tester uncovered more vulnerabilities using the constructed model and in less time compared to using the benchmark OWASP Security Testing Guidelines for mobile Apps model, i.e. it uncovered twenty and eight security vulnerabilities in the MCC HerdFinancial and MCC FourGoats applications respectively. The constructed test case selection technique selects a set of test cases that cover the designated entry points and fit with the user requirements. The results analysis showed that the constructed model has successfully tackled both the complexity and uniqueness of MCC application penetration testing by encompassing these multiple vulnerabilities' domains and MCC offloading. This model can significantly increase the efficiency and effectiveness of the penetration test on MCC applications as the evaluation has shown it has helped the junior tester to uncover 65% more security vulnerabilities within 11% less time compared to the benchmark model. The model evaluation is however limited to SQL injections and XSS vulnerabilities only; nevertheless, these two are the most common vulnerabilities for MCC. The main theoretical contribution is the MCC application penetrating testing model. Likewise, this thesis has two practical contributions, namely the PT2-MCC integrated tool that represents the model implementation and the two MCC test bed applications that can be applied as benchmark MCC penetration testing applications. This thesis is significant because it moderates the lack of testing models to detect security vulnerabilities in the MCC applications and help junior penetration testers to be more effective and efficient when testing MCC applications.

ACKNOWLEDGEMENTS

In the name of Allah, the Most Gracious and the Most Merciful. Alhamdulillah, all praises to Allah for the strengths and His blessing in completing this thesis. Special appreciation goes to my supervisor, Assoc. Prof. Dr. Syed Ahmad Sheikh Aljunid, for his supervision and support. Not forgotten, my appreciation to my co-supervisor, Dr. Normaly Kamal Ismail for his support and knowledge. First and foremost, I have to thank my parents, Salah AlAhmad and _____, for their love and support throughout my life. Thank you both for giving me strength. Finally, and most importantly, I would like to thank my wife Rafa AlAhmad. Her support, encouragement, quiet patience and unwavering love were undeniably the bedrock upon which the past four years of my life have been built. Her tolerance of my occasional vulgar moods is a testament in itself of her unyielding devotion and love.

CHAPTER ONE

INTRODUCTION

This chapter defines the dependability attributes and highlights the problems that motivate this study. It outlines the study's objectives, emphasizes its scope and limitations, and specifies its significance. This chapter provides an overview of the research, including the research background, motivation, problem statement, objectives, questions, scope, significance, and contribution.

1.1 RESEARCH BACKGROUND

The number of clients in both mobile and cloud markets is rapidly increasing. In Malaysia 80% of the population between 20-39 years old own smart mobile phones (MCMC, 2015). In the USA during the first quarter of 2012 more than two-thirds of companies use cloud services or plan to (Babcock, 2012). Due to the high usage of mobile and cloud services, both academics and the information technology (IT) industry have sought to improve and merge both mobile and cloud computing into a single MCC platform.

Among the key implications of cloud computing is the virtualization of the IT platform, infrastructure, software, and applications that are now transformed into cloud delivery services. These cloud service models result in the encapsulation of the whereabouts and the actual state of infrastructure, software, applications, data and/or computation. Delegating these elastic services to mobile technology to minimize limitations and enhance service leads to mobile cloud computing technology (Alizadeh and Hassan, 2013; Bahl and Chaturvedi, 2013; Kottari et al., 2013).

The MCC environment supports multiple technical features such as the integration of on-demand service, dynamic power and virtual resources of cloud computing with the elasticity, restrictions, and interactivity of mobile computing (Alizadeh and Hassan, 2013; Bahl and Chaturvedi, 2013; Kottari et al., 2013).

Consequently, multiple organizations are moving toward building MCC applications. Some of the predominant applications today are MCC applications such as Google mail, Google maps and mobile navigation systems, voice search, MobileMe, LiveMesh, and Motoblur.
