ABSTRACT

Palm oil mill fly ash (POFA) is known to exhibit pozzolanic property. The abundance and easily available of POFA in Malaysia make it an attractive alternative to be fabricated as a ceramic membrane in water treatment. As POFA membrane has high permeability and low selectivity, it is usually coated with graphene. Graphene oxide (GO) and reduction of graphene oxide (rGO) using an environmentally friendly agent was synthesized and the characteristic was studied alongside with POFA membrane. In depth study is done to determine the most suitable composition and casting method to successfully fabricate POFA membrane. The characteristics of the synthesized membranes were performed by using X-Ray Diffraction (XRD), X-Ray Fluorescence (XRF) Spectroscopy, Thermal Gravimetric Analysis (TGA), Fourier Transform Infrared Spectroscopy (FTIR) and Hg Porosimetry Micromeritics. The result revealed that POFA contained high amount of silica which made it pozzolanic with 67.65% porosity. The high porosity of POFA membrane render it as a good choice in wastewater treatment.

ACKNOWLEDGEMENT

First and foremost, I wish to express my deepest gratitude to Allah S.W.T. for giving me the opportunity, strength and ability to embark on my degree and for completing this long and challenging journey successfully. This research could not be done perfectly without His help and guidance.

I would like to give me utmost appreciation to my supervisors Dr. Nur Hidayati Othman and Dr Farid Maulana who had been providing me support and knowledge in completing this thesis.

My appreciation goes to all postgraduate students for the guidance and information regarding on this thesis. I would also want to present my thanks to lab technicians who had assist me in running my sample. Special thanks to all my colleagues of batch 2015 for their moral support and helps with this thesis.

This thesis is dedicated to my mother, _____ who has been working hard to provide me a good education, always believe in me and keep on supporting me from the day one. This thesis is also dedicated to the loving memory of my very dear late father, Norsham Bin Abd. Latif who had always emphasized on the importance of good education for a better future. This piece of victory is dedicated to both of you. Alhamdulillah.

Last but not least, thanks to those who were involved directly or indirectly in supporting me throughout my journey. Thank you.

CHAPTER ONE

INTRODUCTION

1.1 Research Background

Ceramic membrane is preferred over polymeric membrane in wastewater treatment because of its strength since it can be used in aggressive media such as acidic and caustic solution (Lee, Wu and Li, 2015). Therefore, it is durable to degradation and aggressive chemical with pH range 1-14 can be used during cleaning (Jiang, Nordheden and Stagg-williams, 2011). Ceramic membrane has a higher life span due to its unique properties of high thermal, pressure and chemical tolerance. Although ceramic membrane has greater advantages in wastewater treatment than polymeric membrane, capital cost of ceramic membrane is higher than polymeric membrane.

Palm oil mill fly ash (POFA) is used as a substrate in water treatment by fabricating it as a silica source due to its high silica composition (Saharudin *et al.*, 2018). POFA is a by-product of palm oil industries which is obtained after the burning of palm oil fiber, empty fruit bunches and shells which are used as a fuel for palm oil mill boiler in temperature range of 900°C -1000°C (Bamaga, Hussin and Ismail, 2013). It is easily available and environmentally friendly as the improper disposition of POFA leads to health hazard. Therefore, the utilization of POFA minimizes the waste from industrial industry and reduce the probability of pollution and hazard. Besides, POFA is inexpensive as it is an unwanted by-product that is usually discarded after the process.

Graphene oxide which is also known as GO is a film that is produced by oxidation of graphite. It can fabricate from graphite through various methods and modified Hummer method was chosen. GO is widely used due to its high surface area and easiness in manufacturing rather than a graphene. It is also cheap and fluorescent which make it suitable for wastewater treatment application. However, GO is not a good conductor, hence reduced graphene oxide (rGO) is preferred over GO due to its conductivity property. rGO is fabricated by furthering the reduction of GO via thermally or chemically and rGO is fabricated once the oxygenated functional groups from GO are eliminated (Park *et al.*, 2018). Beside from its conductive property, rGO can be stored longer than GO without any agglomeration and it is more stable in organic
