## **ABSTRACT**

Risk management has been established as a well-defined procedure for handling risks due to natural, environmental or man-made hazards, of which floods are representative. Flood risk management is about reducing damages and fatalities. Some large damages, which the population are unable to cover through insurance or savings, can threaten livelihoods. Kuala Lumpur is located in a flash flood prone area. Thus, Kuala Lumpur city experiences flash flood more frequently in this period of time of the years, although flash flood does not always coincide with monsoon seasons every year. Therefore, this study will focus on finding the causes of flood within the city are specifically in Kuala Lumpur. This paper also examined the communities of contractor and developer level of awareness towards risk management of flash flood and also the effectiveness of flood warning measure issued by authorities to reduce flash flood risk. The data will be obtained throughout distribution of questionnaire to 100 respondents, and the data will be supported by interviewing the contractors or developers randomly to ask about flash flood management. Participatory Statistical Program for Social Study (SPSS) is applied to analyze the data that will be obtained throughout questionnaires. Increasing numbers of impermeable lands, inadequate drainage schemes and people's selection of the hazardous flood plains have compounded human activities and exacerbated flood incidents in the presence of natural causes. Strengthening and raising awareness among contractors and developers is necessary as community knowledge is very important to improve preparedness and mitigation to reduce impact due to flood.

## **ACKNOWLEDGEMENT**

With high gratitude to Allah S.W.T. who gave me the ideas and physical strength in preparing this final project/dissertation. Completion of a project of this nature requires more than just the efforts of the author. I wish to express my gratitude to the persons and all parties who responded to the survey and also offered their invaluable contributions in carrying out this final project/dissertation.

First of all, I would like to express my appreciation and acknowledgement to my supervisor who has given me guidance and unfailing support and contribution of ideas in preparing this final project/dissertation. Also, a special thanks for her insightful supervision, encouragement, thoughtful criticisms throughout the research and her creative suggestions.

My gratitude also goes to all those who agreed to be interviewed, formally and informally and gave me the benefit of their knowledge, views and experience. I am also indebted to all my friends for their moral support and encouragement during the preparation of this final project/dissertation.

Finally, I would like to thank my beloved parents and family members, who never stop giving me their encouragement and full support in order for me to complete my final project/dissertation. Thank you for all the understanding given to me when I really needed it.

Thank you.

 <b>CHAPTER THREE: RESEARCH AND METHODOLOGY</b>	

# CHAPTER ONE

## 1.1 Background

Natural disaster is widely known as nature-induced disasters. Such natural disasters consist of volcanic eruptions, earthquakes, tsunamis, avalanches, lahars, landslides, blizzards, heat waves, hurricanes, typhoons, tornadoes, floods, and so on.

Flash flood characterized by high velocity flows and short warning time (Jonkman & Kelman 2005; Ashley & Ashley 2008; Sharesta 2010). Although, some confined the occurrence of flash flood to a specific geographical region such as mountain (Yong Tu et al. 2013), as the impact are more devastating due to the cascading hazard, it also rampant and disastrous to a low land area as well. It is a known fact that flash flood is the most dangerous kind of flood because it combines the destructive power of a flood with incredible speed and unpredictability (Doocy et al. 2013). As these types of floods frequently occur without notice, it often causes extensive damage to infrastructures, the environment, and the loss of lives, further degrading the livelihood and economic prospects of local residents. However, at a higher level, the engineering approach must be seen as integrated in the flood risk management planning decision process. This mechanism includes not only engineers, but also many social classes in society, from government decision-makers to people who are directly exposed to floods. According to Jonkman (2005), flood events caused half million in mortality, and impacted over 3million people from 1980 until 2009. Emergency Event Database (EM-DAT) or Center for Research on the Epidemiology of Disasters (CRED 2009), reported there was a 66 percent global increase of intense hydro-meteorological disasters of 1210 during 1991–2000 to 2004 during 2001–2010 and Asia region is the most affected area by flooding and has the highest casualties per year (Figure 1).
