ACKNOWLEDGEMENT

The author would like to express his sincere thanks to his advisor Puan Siti Hawa Hamzah for her highly valuable guidance, advice , encouragement and comments during the completion of this project. The author also would like to thank to lecturers and staff of Civil Engineering Department for their assistance directly or indirectly towards the completion of the experimental work.

Thanks also to Keretapi Tanah Melayu Berhad, for providing Prestressed Concrete Sleeper for testing, especially, En. Ruslan b. Abu Bakar, from Division of Drawing Office , and staff of KTMB library at Sentul .

The author also would like to thank Dr. Ismail Othman, Head of Civil Engineering Department, Universiti Malaya and technical Staff, Division of Civil Engineering Department, Universiti Malaya, Kuala Lumpur, for their permission and assistance in using the Instrons Testing Machine to make this experimental project possible.

Finally, the author wishes to express his special gratitude to his wife and children who give him their encouragement and moral support during his period of study at Institut Teknologi MARA, Shah Alam.

Author.

ABSTRACT.

The track is the infrastructure of the railway system. In addition to its construction cost, the maintenance cost constitutes an important part of the expenditure in railway management and operation.

A train with a certain wheel load which runs at a certain speed imposes an external force on the track. The means to withstand against this force is provided by the strength of the track structure. The track structure forms a wheel running way, provide maintenance capacity for checking and restoring the deformation and deterioration of the track.

For many years railway line were laid on wooden and metal sleepers. Due to the development of long welded rails and an increase in the train speed, it becomes necessary to increase the weight and strength of the sleepers to resist track buckling and reduce vibration in ballast.

This experimental project is a preliminary study on dynamic testing of Prestressed Railway Concrete Sleepers (PCS). Two specimens were tested; one on the static loading and the other one on the dynamic loading with constant load, to simulate the actual loading condition from axle load of the train.

From the experimental work; results of deflections versus load, deflection versus cycles (hours), stress versus strain, were plotted and location of cracks were shown.
