## ABSTRACT

Transportation is one of the largest energy consumers and the biggest contribution is dominated by the internal combustion engine (ICE). The performance efficiency of the ICE is 30 % for gasoline and 45 % for diesel with almost 65 % of the combusted energy is wasted through the exhaust gas. This exhaust gas is classified as a low grade energy thus recovering it is very challenging. A reliable and feasible recovering system is required to recover this kind of energy. In this study, Organic Rankine Cycle (ORC) is adopted to the powertrain system in order to increase the thermal efficiency. This study evaluates the performance of a condenser that is using ORC in order to achieve 3 kW of heat load. The condenser is also incorporated with ammonia-water mixture as the working fluid to maximize the heat transfer performance. The study focused on characterization of ammonia-water mixture by its thermo-physical properties. In this study, the characterization of ammonia-water mixtures was divided by mol fraction spanning from 0.05 mol to 0.3 mol. The mixtures were identified with six concentration levels which are 5:95, 10:90, 15:85, 20:80, 25:75 and 30:70. The thermo-physical properties of these mixtures, which includes specific heat capacity, thermal conductivity, dynamic viscosity and density, were measured. The test bench was then designed and fabricated according to the specification and limitation of the mixture. Design operating condition was established by obtaining a suitable mass flow rate using the ORC calculation with 25 % and 70 % of thermal and turbine efficiency; respectively. Based on the theoretical thermodynamic calculation, 3 kW heat load was achieved by 36 extruded finned tubes combined with air-cooled condenser design. It was found from the experimentation value that the highest condenser of heat load was only 2 kW at 0.3 mol fraction with 17 % of thermal efficiency. A rapid vaporization of the ammonia was found to be the main factor of the low thermal efficiency.

## ACKNOWLEDGMENT

I owe this thesis to a number of people who have contributed directly and indirectly to the successful completion of the thesis. Firstly, I would like to thank my supervisor, Associate Professor Dr Aman Mohd Ihsan Bin Mamat and co-supervisor, Dr Wan Ahmad Najmi Bin Wan Mohamed for giving me the opportunity to work on this interesting project. Their many words of wisdom, scientific insight and sharp criticism, and high ethical standards are especially valuable for the implementation of this work. I am also grateful for their patience in correcting my thesis and for keeping the pressure on me to finish the thesis within the period.

Further gratitude goes to Faculty of Mechanical Engineering (FKM) UiTM, Faculty of Allied Science UIAM, and Faculty of Mechanical Engineering (FKM) UMP lecturers and students who offered tips, advice and endless cooperation in this project. To those involved, you all deserved a sincere thank you from me. My fellow postgraduate students should also be recognized for their support. My sincere appreciation is also extended to all my colleagues and others who have provided assistance at various occasions. Their views and tips were useful indeed. Unfortunately, it is not possible to list all of them in this limited space.

Finally, this thesis is dedicated to my beloved husband, my lovely son and my parents for the vision and determination to educate me. The piece of victory is dedicated to all of you. Alhamdulillah.

# CHAPTER ONE

## INTRODUCTION

### 1.1 Background of Research

The level of energy consumption is directly proportional to the economic development and total number of population in country as referred to the socio-economic perspective. Between 2010 to 2020 energy demand is expected to increase approximately 11 % with population growth [1]–[3]. Figure 1.1 shows a table of percentage values for transportation sector in 2012 with 37 % of total energy consumed in the Malaysian transportation sector [4]. Transportation industries have received much attention because it contributes the highest energy usage in Malaysia. The energy used are contributed by various types of transportation from personal and commercial vehicles. The large energy growth is caused by growing number of passengers, operating time of vehicle and increasing in trip length due to demand [5]. Construction and manufacturing sectors contribute towards the industrial sector and they consume about 30% of energy used. This factor is caused by a high demand of technologies development.
