## ACKNOWLEDGMENT

First and foremost, praise to ALLAH s.w.t for his blessings and mercy for giving me an excellent health in completing this project. I would like to express my gratitude to many parties. My heartfelt thanks go to my supervisor, Dr Ab Malik Marwan Ali and my Co. supervisor, Dr Muhd Zu Azhan Yahya for their time consuming in guiding and improving the content of my final project report, for being understanding regarding on the problem face and provided more time upon completion of this project. I gratefully acknowledge for the opportunity to be supervised by them.

I am also highly thankful to En Nazli, Project Coordinator of B.Sc.(Hons) Physics programme, for giving helpful information, guidance and suggestions regarding the content of this project, I gratefully acknowledge the detailed work on supervision, assessment, evaluation and format for student project.

My warmest thanks are due to my father Mohamed Ariffin Bin Abdul Hamid and mother, Salmah Bt. Salleh and my sibling Noraini, Norol and Muhammad Hirman for helping, understanding, patient and never-ending support and encouraging all this time.

Furthermore, I express my gratitude to my course mate in Physics and all individual that have contributed ideas, comment, and criticized for having made my time in completing this project so enjoyable, thank you so much.

Last but not least, I would like to thank University Teknologi MARA Shah Alam, especially Faculty of Applied Sciences for providing the facilities and wonderful education.

Norkhairul

## ABSTRACT

Composite gel polymer electrolyte consist of cellulose acetate (CA), aluminum per chlorate ( $\text{Al}_3\text{ClO}_4$ ), dimethylformamide (DMF) solvent and silicon oxide ( $\text{SiO}_2$ ) filler have been prepared. Liquid electrolyte composing of different molarities  $\text{Al}_3\text{ClO}_4$  in DMF solvent have initially been prepared. The highest conductivity obtained for this system is  $6.11 \times 10^{-3} \text{ Scm}^{-1}$  when the selected 0.9M liquid electrolyte is introduced. Upon the addition of 5wt% of CA as polymeric gelling agent into the selected 0.7M liquid electrolyte, the conductivity is enhanced by  $\sim 21\%$  to the maximum of  $4.85 \times 10^{-3} \text{ Scm}^{-1}$ .  $\text{SiO}_2$  is added into the highest conductivity gel polymer electrolyte system in order to increase the mechanical properties. The highest conductivity obtained for the composited polymer electrolyte is  $6.12 \times 10^{-3} \text{ Scm}^{-1}$  when 3wt%  $\text{SiO}_2$  is added. The highest conducting composited polymer electrolyte sample is then chosen as an electrolyte in fabrication of aluminum air cells. The cells have been characterized according to their open circuit voltage (OCV). It has been found that the initial OCV at 1.65 V is obtained and constant at  $\sim 1.3$  V for more than 24 hours.

## CHAPTER 1

### INTRODUCTION

#### **1.1 Background**

Metal/air batteries show a high energy density, a flat discharge voltage and long shelf life. As such zinc is an excellent metal for use in a metal/air battery because of its stable in alkaline electrolytes. Metal/air batteries either use alkaline or neutral electrolytes. Other metals such as lithium, calcium, magnesium, aluminum, or iron may be used in metal/air batteries.

In metal/air batteries, the reactive anode and air electrode result in an inexhaustible cathode reactant. The performance of these batteries can be affected in several ways. Limitations in the oxygen or air electrode of metal/air batteries cause voltage to decrease sharply with increasing current; therefore, these batteries are appropriate for applications that require low to moderate power. Carbon dioxide can be absorbed by the battery, which may lead to carbonate crystallization in the air electrode, decreased performance, and may cause damage. Systems recharged electrically allow the oxidation of catalysts and electrode supports during charging. In addition, an effective air electrode must be utilized for adequate performance.
