## ABSTRACT

Geometric morphometric is a new method used by anthropologists in examining shape analysis. The traditional measurement of malocclusion relies on cephalometric techniques. Nowadays, the geometric morphometrics method (GMM) for shape analysis could provide better perception and capabilities of measuring the size and shape variations of malocclusion in 2D and 3D dimensions.

This study aims to investigate the size and shape and its variations of hard and /soft tissue patterns in different skeletal relations in adult Malays using the 2-dimensional (2D) geometric morphometrics method from lateral cephalograms. In this study, a total of 188 lateral cephalograms of Malaysian Malay (age 18–40 years) were collected and comprised of Class I, Class II, and Class III skeletal relations with 117 females and 71 males. A total of 21 2D-dimensional hard tissue and soft tissue landmarks were applied on lateral cephalograms using tpsDig2 software version 2.31. The MorphoJ software version 1.07a was used for the data and shape analysis. The data were analysed for shape variation according to skeletal relations and gender groups. As a result, 18 shape variations for soft tissue and 16 principal components (PC) for hard tissue variations were produced. Centroid size was significantly different in genders and skeletal relations by Procrustes ANOVA ( $P < 0.01$ ). Canonical variate analysis (CVA) showed the highest Mahalanobis distances and Procrustes distances between Class II and III among skeletal relations and between males and females ( $P < 0.0001$ ). Discriminant function analysis (DFA) among skeletal relations showed the classification was mostly accurate, especially for Class II and Class III with success rates of 92.1% and 88.3%, respectively, after cross-validation. The highest percentages of success rates were 85.4% for females and 87.3% for males after cross-validation among skeletal relations.

In conclusion, there were different ANB angles in different skeletal relations. Class III showed the most protrusive upper and lower lips, while class II demonstrated the most retrusive lower lip. The result of this study could be used to develop an artificial intelligence system for predicting the skeletal and facial morphology of Malay subjects as a guide in diagnosis and treatment planning for orthodontists and maxillofacial surgeons.

## ACKNOWLEDGEMENT

First and foremost, I thank Allah for giving me the opportunity to embark on my Master`s program and for completing this long and challenging journey successfully. I would like to express my sincere gratitude to my respected supervisors Dr. Naghah Mohammed Abdullah Al-Jaf, Dr. Noraina Hafizan Norman, and Dr. Aspalilah Alias, for their invaluable supervision, continuous support, and patience, who have helped me throughout this research project and master program journey.

I would like to extend my sincere thanks to the Ministry of Higher Education of Afghanistan, Kabul University of Medical Sciences, and Higher Education Development Program (HEDP), who sponsored and supported me in pursuing the Master`s program in Malaysia.

Lastly, I am heartily thankful to my parents, brothers, and sisters, without the encouragement of whom it would be impossible for me to complete my studies. I also appreciate all the support I received from the rest of my family and friends.
