ACKNOWLEDGEMENTS

Alhamdulillah, all praises, glory and thanks to Allah, the almighty Lord of the world. Peace and blessing to Nabi Muhammad S.A.W., all the Prophets, his families and all muslims.

I would like to express my special appreciation and thanks to my supervisor, Mr. Mohd. Nasri bin Abd. Rahman for his untiring guidance and advice throughout the course of this study. I will always be grateful to his advice and guidance on experimental design, detailed assistance, and kind encouragement. Without his supervision and constant help, this thesis would not have been possible.

In addition, I would especially like to thank all the lab assistants at Faculty of Science Laboratory, UiTM Pahang who in many ways contributed to the success of my research. Not forgetting fellow classmates who have also gave valuable advices and suggestions in completing this project.

Last but not least, I would like to express the deepest appreciation to my parents, Farush Khan bin Akbar Khan and Mussawar Jahan binti Ghulam Rasool and my sisters, for their endless pray, support and encouragement throughout this project.

Farah Izzati binti Farush Khan

ABSTRACT

THE EFFECT OF RADICAL SCAVENGING ACTIVITY ON ORANGE G DYE DEGRADATION PROCESS USING FENTON'S REAGENT

Wastewater is exhausted in large volume every year due to the processes of textile industries such as dyeing and finishing processes. Nowadays, more than 50% of dyes used in textile industry are Azo-based dyes. Inorganic salts improve the coloration of the dye, which enhances the pollution load of wastewater from textile industries. Degradation of the reactive textile dye Orange Gelb (OG) was studied using Fenton's Reagent of Advanced Oxidation Processes (AOPs). A laboratory set-up was designed to evaluate the effectiveness of Fenton's Reagent process. The initial concentration of OG in the reaction was 10^{-4} M. The effects of irradiation time and the addition of different types and concentrations of inorganic salts (NaCl, NaHCO₃, NaNO₃ and Na₂CO₃) on the degree of degradation efficiency were studied. The results indicated that photo-Fenton's process is more effective than Fenton's process without UV irradiation in dye degradation process. Photo-Fenton's process degrades the dye up to 86%, whereas Fenton's process without UV irradiation only degrades the dye up to 72%. On increasing the Na₂CO₃ and NaHCO₃ salts concentration to 1 M, the percentage decolorization decreased to 24% and 18% respectively. The presence of NaNO₃ salt barely affects the degradation efficiency of the dye. On increasing the salt concentration to 1M into the dye solution, the percentage decolorization only decreased to 80%. On the addition of 1 M NaCl salt, the degradation efficiency decreased to 74% and by the addition of 10^{-4} M NaCl salt, the degradation efficiency increased to 88%, 6% higher than the degradation efficiency of photo-Fenton's process, due to the formation of hypochlorite ion from the chloride ions. Additionally, it was found that all salts in this experiment could inhibit the efficiency of OG degradation and the degree of their scavenging effects can be ranked from low to high in an order NaNO₃ < NaCl < Na₂CO₃ < NaHCO₃.
