How to compute a mean (or average) variable using SPSS

Written by: Dr. Nur Izzah Binti Jamil

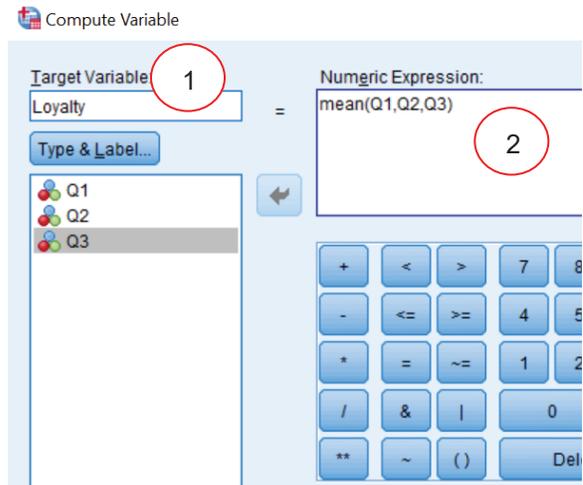

This article will show on how to compute a mean (or average) variable from a set of variables in SPSS. For example, we have perception scores (out of 5) on different variables. There are scores on variables Q1, Q2, and Q3 from 8 respondents.

	Q1	Q2	Q3	var
1	4	4	5	
2	5	3	5	
3	5	4	4	
4	4	3	4	
5	5	5	5	
6	4	3	4	
7	4	4	4	
8	5	5	4	
9				
10				

In SPSS, go to **Transform > Compute variable**

1. Enter the name of the new variable to be created in the **'Target Variable'** box. For example, Loyalty.
2. In the **'Numeric Expression'** box, type the function **'mean()'**. Within the brackets of the mean function, double-click on the variables listed in the box to the left of the window, separating each one with a comma.

3. Click the **'OK'** button to compute the mean variable.

4. The new variable of **'Loyalty'** should appear in the data view. This value will then be the mean of the variables entered (Q1, Q2, Q3) into the function.

	Q1	Q2	Q3	Loyalty
1	4	4	5	4.33
2	5	3	5	4.33
3	5	4	4	4.33
4	4	3	4	3.67
5	5	5	5	5.00
6	4	3	4	3.67
7	4	4	4	4.00
8	5	5	4	4.67

5. Easy peasy lemon squeezy.
