## ABSTRACT

The escalation of photovoltaic (PV) system installations has led to the development of PV software simulation tools, which are valuable for optimizing the design of PV systems.. However, one common issue related to simulation is the accuracy of the simulation with respect to the actual system performance. It is crucial to evaluate the accuracy of these simulations concerning the actual system performance. Analysis on several retrofitted grid-connected PV (GCPV) systems using PVsyst software also highlighted the significance of thermal loss ( $T_{\text{loss}}$ ) as the major system loss, which reached up to 14%. Nevertheless, the comparison between the actual and simulated  $T_{\text{loss}}$  for GCPV system is still very limited, particularly in Tropical Rainforest Climate of Malaysia. Therefore, this study presents the evaluation on the design configuration of the actual installed and PVsyst simulated, comparison of the actual and PVsyst simulation technical performance and estimation of the discrepancy between actual and PVsyst simulated thermal loss of three GCPV systems in Malaysia. The results showed similarity between the simulated design configurations and the actual installed systems. The technical performances of systems A, B, and C were evaluated for the year 2019, considering seven parameters: DC energy generated ( $E_A$ ), AC energy generated ( $E_{\text{out}}$ ), Array yield ( $Y_A$ ), final yield ( $Y_f$ ), reference yield ( $Y_r$ ), performance ratio ( $PR$ ), capacity factor ( $CF$ ). The results demonstrated a generally good agreement between the simulated and actual values for annual  $E_A$ ,  $E_{\text{out}}$ ,  $Y_A$ ,  $Y_f$ ,  $Y_r$ ,  $CF$  with the Mean Bias Error (MBE) being less than 10% for all parameters. However, it is worth noting that the simulated annual  $PR$  exhibited the most significant inaccuracy. The MBE between the actual and simulated values for  $PR$  was -7.9%, -13.7%, and -11.4% for systems A, B, and C, respectively. The discrepancy can be attributed to an overestimation of losses declared in the PVsyst simulation, leading to the inaccuracy of the simulation results. Another potential factor contributing to the underprediction of  $PR$  is likely the  $T_{\text{loss}}$ , which the actual values for system A, B and C were found to be 8%, 6%, and 6.4%, respectively. On the other hand, the simulated  $T_{\text{loss}}$  obtained for systems A, B, and C were 11.7%, 11.7%, and 11.5%, respectively. When comparing the simulated  $T_{\text{loss}}$  to the actual  $T_{\text{loss}}$ , the results revealed that the simulated values were consistently higher for all three systems, with a deviation of 3.7%, 5.8%, and 5.1% for systems A, B, and C, respectively. This study has successfully compared the actual and PVsyst simulated  $T_{\text{loss}}$ , leading to the proposal of further modifications to the field  $T_{\text{loss}}$  based on the type of mounting in PVsyst simulations.

## ACKNOWLEDGEMENT

In the name of Allah, the Most Gracious, the Most Merciful, I extend my profound gratitude to Allah for the successful conclusion of this master's thesis.

Foremost, I wish to express my sincere appreciation to my primary supervisor, Associate Professor Dr. Hedzlin Zainuddin, for her invaluable guidance, relentless supervision, and unwavering encouragement. I am deeply grateful for her constructive insights, invaluable advice, and consistent support throughout the trajectory of my research endeavour.

I am also indebted to my co-supervisor, Ts. Dr. Mohamad Zhafran Bin Hussin whose moral backing, insightful critiques, and collaboration played an indispensable role in shaping this thesis. I am sincerely thankful for the encouragement and enthusiasm exhibited by my supervisor and co-supervisor.

I am also grateful to the member of SPECTRA and GERC for the facilities and knowledge sharing throughout the journey. Gratitude also extends to my colleague Siti Nor Nadhirah Ibrahim for their unwavering help, support, and shared dedication.

Lastly, I am deeply indebted to my father, Abdul Rahim Ahmad, and my mother, [REDACTED], for their unwavering economic support and constant encouragement at every step of this endeavour. Likewise, I extend my heartfelt appreciation to my siblings, relatives, and friends whose unwavering support played a significant role in this achievement.

I humbly dedicate this accomplishment to all those who have contributed to my journey. Alhamdulillah, this triumph is a reflection of our collective efforts and dedication.

# CHAPTER 1

## INTRODUCTION

### 1.1 Research Background

Malaysia possesses a geographically advantageous location for the generation of solar energy, primarily due to its proximity to the equator (Shafie et al., 2011). This strategic positioning allows the country to receive substantial solar irradiance, ranging from 1,575 kWh/m<sup>2</sup> to 1,812 kWh/m<sup>2</sup>, which is comparable to the regional average of 1,500 kWh/m<sup>2</sup> to 2,000 kWh/m<sup>2</sup> observed in Southeast Asia (SEDA, 2021)

The exceptional solar potential in Malaysia has rendered it as an ideal location for solar energy generation, with various types of solar photovoltaic (PV) installations available, including rooftop, ground-mounted, and floating solar PV. This high solar irradiance, increase the potential for solar PV installations in Malaysia particularly grid-connected PV (GCPV) with an estimated 42 GW of rooftop solar PV resource availability from 4.6 million buildings and 43 university campuses, while ground-mounted solar PV has the highest solar potential in Malaysia at 210 GW. Additionally, floating solar PV has an estimated 16.6 GW of resource potential available in Malaysia, covering 17 hydroelectric plants and 62 reservoir dams that make up 2,944 km<sup>2</sup> of total water surface area (SEDA, 2021)

The rise in PV system installations within Malaysia has led to an increased utilization of commercial PV software simulation tools. These tools play a crucial role in optimizing the design and performance of photovoltaic systems, ensuring their maximum efficiency and effectiveness (González-Peña et al., 2021; Umar et al., 2018). Various software applications such as PVsyst, HOMER, MATLAB, and others have been employed for simulation and analysis purposes (Al-Waeli et al., 2018; Dondariya et al., 2018; Duman & Güler, 2020). These studies commonly analyze parameters including energy production, reference, array and final yield, performance ratio, capacity factor, system efficiency, and system losses (Allouhi et al., 2016; Ameer et al., 2020; Attari et al., 2016; Dondariya et al., 2018; Duman & Güler, 2020; Emziane & Al Ali, 2015; Omar & Mahmoud, 2018; te Heesen et al., 2019). This study aims to compare the actual and simulated technical performance parameters of three GCPV systems in Malaysia and subsequently estimate the discrepancies in thermal loss between the actual
