ABSTRACT

This study aimed to analyse and evaluate the effect of the additive of ascorbic acid(AA) on the properties of the produced sago starch-based edible film. Tests were run on the films with and without ascorbic acid to determine the mechanical strength, thickness, solubility of films, antioxidant activity and color. The higher concentration of AA in sago starch film shows the higher solubility compared to film without AA. It was also shown the decreasing in tensile strength and increasing in elongation on film. The water vapor permeability of films with the AA concentration was lowest. Besides, the concentration of AA in films affect antioxidant activity as it has higher percentage of radical scavenging activity (98.5%) meanwhile the colour of the film with AA is yellowish as the degradation of AA presence in film.

ACKNOWLEDGEMENT

First and foremost, I would like to thank my research supervisors Madam Fariza Hamidon. Without her assistance and dedicated involvement in every step throughout the process, this paper would have never been accomplished. I would like to thank you very much for your support and understanding throughout my study periods.

Besides that, I would like to express my gratitude to my friends for getting their endless support through my thesis. Thank for listening to and, at times, having to tolerate me over the past 4 years.

Most importantly, none of this could have happened without my family. Thank you for showing me with unfailing assistance and endless encouragement throughout my years of research and through the research and writing phase of this thesis. Without them, this achievement would not have been true. Every time I was ready to quit, you didn't let me and I'm always thankful. This thesis is a testament to your unconditional love and encouragement.

CHAPTER 1

INTRODUCTION

1.1 RESEARCH BACKGROUND

Production of plastic resources has established a rapidly growth for more than 50 years in the world. It is predictable that these materials production increase to 300 million tons. (*Piñeros-Hernandez et al 2017*) Plastic is one of the main material that used for food packaging over a years. Thus, there are likely have waste disposal problems because of the usage of more plastics that are not readily biodegradable and lead to microbial deprivation, petroleum-derived plastic accumulates in the environment. (*Yoon, 2014*). Besides, natural polymeric materials such as fossil fuel also have been used as food packaging same as plastic. Unfortunately, these fossil fuels are non-renewable and most of them non-biodegradable. (*Otoni et al., 2017*).

In recent years, edible films have received significant attention because of edible packaging materials over synthetic films advantages. (*Bourtoom, 2008*) Though the
