## ABSTRACT

In this study, Emulsion Liquid Membrane (ELM) was used for copper and cadmium removal in Taylor-Couette Column (TCC). ELM is a double emulsion of water/oil/water (W/O/W) system consists of three main phases which are membrane phase, internal phase and external phase, while TCC was used to obtain a better mixing condition with a uniform and relatively low fluid shear to maintain the emulsion stability. The chemicals used in this study are Bis(2-ethylhexyl) phosphate (D2EHPA) as carrier, Span 80 as surfactant, kerosene as diluent and hydrochloric acid (HCl) as internal phase. Meanwhile, copper nitrate ( $\text{Cu}(\text{NO}_3)_2$ ) and cadmium nitrate ( $\text{Cd}(\text{NO}_3)_2$ ) solution were used as the external phase. The extraction of copper was executed in a counter rotating TCC and samples were analyzed using Atomic Absorption Spectrophotometer (AAS) to determine the copper and cadmium concentration in external phase. This research was done to study the mixing of water-oil-water (W/O/W) emulsions in Taylor-Couette flow and to identify the best condition to achieve high copper and cadmium removal using ELM in TCC. The parameters involved are the external phase pH, extraction time and rotational speed of the TCC outer cylinder. It was found that pH 4 was the most optimum pH to achieve the maximum extraction efficiency of copper (92.72%) and cadmium (81.29%). While the highest efficiency for copper was at stirring speed of 200 rpm in 5 minutes (96.38%) and cadmium at 600 rpm in 3 minutes (81.59%).

## **ACKNOWLEDGEMENT**

First and foremost, I would like to express my highest gratitude to Allah, Lord of the World for giving me the opportunity to pursue my study in Bachelor Degree level and for the strength to complete this research project. I am forever thankful for all the good and hard times He gave during this journey in order to shape me into a better person.

Special thanks to my supervisor Sir Meor Muhammad Hafiz Bin Shah Buddin for all his sincere effort in perfecting my works and his utmost patience in guiding me throughout the process. In reward for all his kindness in helping me, I pray that may Allah repay him with more knowledges and happiness both in this world and hereafter.

Deepest gratitude to my parents Abd Khalil and for being my best friends and my biggest supporters. Thank you for never giving up on me and have always been motivating me all the way. This thesis is dedicated to both of them who will forever be my reason to stay strong.

My appreciation goes to my closest friends Fathin Nor Faridah, Nor Azmah and Fatin Najwa who were there for me to share knowledges and challenges throughout my study process. Thank you for walking with me together in this journey while strengthening each other. Not to forget my sister, Aqilah Faqihah and my friends who have sincerely supported me physically and emotionally for all this while.

Thank you and may Allah repay all of you with the best rewards possible.

# CHAPTER ONE

## INTRODUCTION

### 1.1 Research Background

Reducing hazardous metals content in liquid effluent streams has already been a general discussion nowadays. Virulent heavy metal ions commonly found in discharged industrial waste water has been of great concern to not only the environment, but also towards humans' health. It is no doubt that in the forthcoming future, the problem of heavy metals exhaustion originated from industry will be getting worse in the entire globe (Othman et al., 2018).

According to the World Health Organization, WHO (2011), some of the metals with the greatest concern include copper, aluminum, arsenic and cadmium. Heavy metals are non-biodegradable in nature; hence they have the tendency to be accumulating in living creatures, which leads to several disorders and diseases (Liu et al., 2007). Copper(II) ions are released in huge amounts into the open water in environment through the wastewater originated from various industries such as steelworks, metallurgy, mining, plating, petroleum refining, paper and pulp, wood preservatives, fertilizer and circuit printing (León et al., 2017). Other than that, cadmium exists naturally as a minor constituents of base metal ores and coal deposits, and also exists as a toxic heavy metal found in industrial discharges of various industries such as manufacturing of cadmium, nickel batteries, phosphate fertilizers, pigments, stabilizers, alloys and electroplating industries which is very harmful towards the environment (Mortaheb et al., 2008). In the way to overcome the barrier towards a sustainable future with favorable environment, many methods are issued by researchers to extract heavy metals from waste water. The way to achieving the most perfect method however, is still too far with most of the methods proposed still need to be improved.

Liquid membrane process was proposed as one of the promising techniques to overcome those problems, where it offers a potentially powerful technique for metal separation and recovery. Some special feature of liquid membrane extraction that are not in conventional membrane processes includes simple operation, high efficiency,
