ACKNOWLEDGEMENTS

In the name of Allah, the compassionate, the merciful. All praises are due to Allah. First and foremost we thank Allah, the Generous, for having finally made this humble effort to a reality, give us strength and courage to us until this research completed. And, we would like to express our deepest gratitude to all those who contributed directly or indirectly to bring this research completely success. We would like to thank to Research Management Institute (RMI), Universiti Teknologi MARA (UiTM) in giving the funding through Excellent Fund for this research. This appreciation also goes to our student, 'Ali Syari'ati Bin Mohd Salleh due to his contribution in our research. We are also grateful to those people encouraging us to improve on our best and thanks especially to our beloved parents and family and all colleagues.

ABSTRACT

In mobile robot navigation, Global Positioning System (GPS) plays a major role in providing and finding the best path for the robot to navigate. Navigation is very crucial due to the robot ability to adapt and sustain to its environment and find its path to the target location. This research proposed mobile robot navigation using GPS to cope for the navigation problem in reaching the target location. The data received from GPS is processed and hence the decision is made for the robot navigation path by the algorithm applied in the microcontroller. The path finding algorithm will basically find the best path and instructs the robot to move to its location by keep on refreshing its positions. Certain rules need to be applied in the microcontroller to utilise its decision thoroughly. The hardware consists of two DC brushless motor with four rear wheels to provide motion to the robot. The hardware design that has been chosen is basically based on military tank concept and used different drives system to trigger the motion. The PIC microcontroller is used as the brain to perform all the control action and GPS act as the main sensing unit for the robot. The short distance test has been made to evaluate the mobile robot path finding performance. The result showed the average of 6.34 meter for the error in radius. Improvement in the mechanical design as well as the path finding algorithm might improve the accuracy in the future.
