

Gel Polymer Electrolytes base on Cellulose Acetate for Lithium Batteries

Mohd Afiza Bin Che Mustapha

**Final Year Project Report Submitted in
Partial Fulfillment on the Requirements for the
Degree of Bachelor of Science (Hons.) Physics
in the Faculty of Applied Sciences
Universiti Teknologi MARA**

NOVEMBER 2008

ACKNOWLEDGEMENT

First of all, thanks to Allah SWT. At last, I could finish this proposal on time. It takes a lot of sincerity. Upon completion of this project, I would like to express my gratitude to many parties. My heartfelt thank goes to my supervisor: Dr Ab Malik Marwan Ali and my co-supervisor Dr. Muhd Zu Azhan Yahya for shedding light on difficult points and problems, for their patient guidance, encouragement and excellent advices throughout this proposal.

The same gratitude goes to master seniors and other parties that given a lot of contribution through this research. I take this opportunity to express my profound gratitude to those influential people around me who always motivate me to achieve more and more.

Finally, I want to express my recognition to University Teknologi MARA for giving me the opportunity to further my study at this level.

ABSTRACT

GEL POLYMER ELECTROLYTES BASE ON CELLULOSE ACETATE FOR LITHIUM BATTERIES

The electrolyte conductivity and electrochemical stability are key parameters in selecting suitable electrolyte in order to fabricate lithium battery. Cellulose acetate (CA) was used as the polymer, SiO₂ as the filler and LiBF₄ was dissolved in 20ml DMF as lithium salt and solvent respectively. Gel electrolytes with various concentrations of LiBF₄ and various weight percentages of CA and SiO₂ have been prepared. The conductivity was studied using complex impedance spectroscopy to investigate ionic conductivities in DMF-LiBF₄, DMF-LiBF₄-CA and DMF-LiBF₄-CA-SiO₂ electrolyte systems. The highest conductivity was found at 9.0M LiBF₄ in the DMF-LiBF₄ systems with conductivity of $(8.01 \times 10^{-3} \pm 0.00) \text{ Scm}^{-1}$. In the DMF-LiBF₄-CA system with composition of 2 wt. % CA exhibited the highest conductivity of $(7.51 \times 10^{-3} + 2.00 \times 10^{-4}) \text{ Scm}^{-1}$, and the value was enhanced to $(7.88 \times 10^{-3} \pm 2.20 \times 10^{-4}) \text{ Scm}^{-1}$ when 0.1 wt. % of SiO₂ was added.

CHAPTER 1

INTRODUCTION

1.1 Background

Lithium batteries are disposable (primary) batteries that have lithium metal or lithium compounds as an anode. Depending on the design and chemical compounds used, lithium cells can produce voltages from 1.5 V to about 3.0 V, twice the voltage of an ordinary zinc-carbon battery or alkaline cell.

Lithium batteries have dominated the field of advanced power source and replace many other batteries in the market, particularly in the area of communication, computer, electronics, and in more power demanding devices such as power tools and transportation. With dramatic increase on the size of the battery pack, there are growing in the significant progress of lithium batteries is mainly due to the numerous innovations in materials, design, and safety aspect of the batteries[1].

The term "lithium battery" refers to a family of different chemistries, comprising many types of cathodes and electrolytes. Recently, there are enormous active research have been done on the electrolytes for advance lithium batteries. The basic requirements of a suitable electrolyte for electrochemical devices are high ionic conductivity, low melting and high boiling points, chemical and electrochemical stability, and safety [2].
