## AUTHOR'S DECLARATION

I declare that the work in this thesis was carried out in accordance with the regulations of Universiti Teknologi MARA. It is original and is the results of my own work, unless otherwise indicated or acknowledged as referenced work. This thesis has not been submitted to any other academic institution or non-academic institution for any degree or qualification.

I, hereby, acknowledge that I have been supplied with the Academic Rules and Regulations for Post Graduate, Universiti Teknologi MARA, regulating the conduct of my study and research.

Name of Student : Mohd Shahrizi Bin Razali

Student I.D. No. : 2015461924

Programme : Master of Science (Chemical Engineering) – EH750

Faculty : Chemical Engineering

Thesis : Scale-up of Microalgae Growth from 1 L Flask to 60 L Fed-batch Raceway Pond (FRP) and its Growth at Quasi-steady State in POME Medium

Signature of Student :  .....

Date : April 2020

## ABSTRACT

Microalgae cultivation system has been proposed to be incorporated into palm oil industry for simultaneous palm oil mill effluent (POME) bioremediation and CO<sub>2</sub> sequestration. In this context, raceway pond is the most suitable cultivation method to be used nevertheless its tendency to degas the supplied dissolved carbon dioxide (DCO<sub>2</sub>) into the atmosphere. Accordingly, a 220 L Fed-batch Raceway Pond (FRP) was designed to address this problem where it embodies a variable-volume fed-batch culture [from 60 L (batch stage) to 220 L (fed-batch stage)], with a movable-semi-circular barrier for ensuring a constant liquid depth level, a movable vertical flow separator for flow circulation, a variable-speed paddlewheel for flow generation, and a membrane contactor for the carbonation of fresh growth medium. The first objective of this study include determining the growth kinetics of *Chlorella* sp. UKM2 in untreated POME medium at various CO<sub>2</sub> levels in 1 L flask in order to provide information valuable to the design and operation of the FRP. Secondly, this study attempts to scale-up microalgae growth from 1 L flask to 60 L FRP, and subsequently to demonstrate its growth at quasi-steady state in fed-batch stage of the FRP. In the first experimental part which involved *Chlorella* sp. UKM2 cultivation in 1 L flask showed that its maximum specific growth rate ( $\mu_{\max}$ ) in untreated POME medium with 10,000 lux lighting has a maximum value of 1.18 d<sup>-1</sup> at CO<sub>2</sub> level varied from 0.04–10% (v/v). Following that, the scale-up of *Chlorella* sp. UKM2 growth at 60 L FRP scale was attempted with Bold's basal Medium (BBM) through a stepwise experimental approach. However, the attempt failed and the problem areas were narrowed down to be related with variables mixing and inoculum, as identified through The Monitor Experiments, given the mixing in the FRP was not able to sustain *Chlorella* sp. UKM2 in suspension resulting in its sedimentation and collapsed, nonetheless that the said variables have been upgraded to reach their operational limits from 2,500 lux to 10,000 lux and from 4-bladed, fixed-speed, paddlewheel to 8-bladed, variable-speed paddlewheel, respectively. In the same operational conditions, scale-up was again conducted with *Scenedesmus* sp. UKM9, and appropriate growth with maximum biomass concentration ( $X_{\max}$ ) of 1.067 g/L and  $\mu_{\max} = 0.2842$  d<sup>-1</sup> was obtained, even though considerable difference against the 1 L flask scale cultivation was still observable in particular to its half reduction in its biomass productivity. Thereafter, *Scenedesmus* sp. UKM9 cultivations at fed-batch stage of the FRP were demonstrated using BBM and POME medium, where both cultivations reached quasi-steady state since their biomass concentration ( $X$ ) remained fairly constant at  $0.92 \pm 0.04$  g/L and  $0.42 \pm 0.036$  g/L when dilution rate ( $D$ ) was set at 0.0792 d<sup>-1</sup> and 0.14 d<sup>-1</sup>, respectively. The CO<sub>2</sub> recovery ( $C_{\text{recovery}}$ ) for both cultivations was determined at 115.29% and 129.6% respectively, based on assumption that *Scenedesmus* sp. UKM9 in the culture conducted growth entirely by photosynthesis. The more than 100% recovery obtained in this study signifies that all the supplied DCO<sub>2</sub> had been captured in the quasi-steady state growth and incorporated into the biomass, and none degassed out from the liquid culture, with some CO<sub>2</sub> dissolved from the atmosphere too being captured and incorporated into biomass, bridging the recovery to higher than 100%.

## ACKNOWLEDGEMENT

My most gratitude to Allah SWT, the Almighty for giving me the great chance to enhance my knowledge and to complete this research. May the peace and blessing be upon Prophet Muhammad SAW.

I would like to express my appreciation to my respected supervisor, Prof. Ir. Dr. Jailani Salihon. His helpful advice, constant encouragement, invaluable guidance and effective support did help me indeed in making this research possible and complete. The same also goes to my co-supervisor Dr. Tan Huey Ling.

I highly value the support from all staffs in the Faculty of Chemical Engineering, Universiti Teknologi MARA during the study period. I would like to highlight Mr. Afzal, Mr. Aziz, Ms. Hajatun, Ms. Adibah, Dr. Putri Nadzrul, and Dr. Siti Shawalliah.

Finally, an utmost appreciation to my parents, Seniah Satem and Razali Morni for their patience, infinite inspiration, absolute love and constant support to me.
