ALOE EMODIN REGULATES THE SUPPRESSION OF
BREAST CANCER CELL PROLIFERATION VIA CALCIUM
SIGNALLING

MOHD RIDZUAN BIN HAMID

AUGUST 2012

ACKNOWLEDGEMENTS

Assalamualaikum w.b.t.,

First and foremost, I would like to say Alhamdulillah and utmost grateful to Allah S.W.T for giving me chances to complete this project and also the completion of this thesis.

I am sincerely thank to my supervisor, Dr. Siti Hamimah Binti Sheikh Abdul Kadir, who is an amazing mentor and who is my major advisor for always being there to support me with good guidance and valuable sights. Also, I would like to appreciate for all the helps and suggestions and also ideas provided by my co-supervisors, Dr. Narimah Abdul Hamid Hasani and Dr. Rosfaiizah Siran.

Apart from that, I am entirely indebted to Dean of Faculty of Medicine of UiTM, Prof. Dato' Dr. Khalid Haji Yusoff, and also to coordinator of MBBS with Advance Medical Science programme, Prof. Dr Mohammed Nasimul Islam for providing mentorship and encouragement that has undoubtedly provided me with inspiration for future endeavours. Acknowledgment must also go towards UiTM for funding this project through Dana Kecemerlangan and also Fundamental Research Grant Scheme (FRGS) grant.

I also would like to take the opportunity to thank to both of my parents,
and and also to all my siblings for having faith in me and encouraging me.

2.1.1 Chemicals used in cell culture and experiments	31
2.1.2 Solutions for cell culture	32
2.1.3 Instruments	34
2.2 Methods	34
2.2.1 Cell culture	34
2.2.2 Passaging of the cell lines	35
2.2.3 Cryopreservation and Cell Revival	35
2.2.4 Cell count and cell viability experiments on MCF-10A and MCF-7 cells	36
2.2.4.1 Seeding of the cells	36
2.2.4.2 Aloe emodin and tamoxifen preparation	36
2.2.4.3 Cell preparation and treatment	37
2.2.4.4 Harvesting the cells	39

ABSTRACT

Deregulation of Ca^{2+} signaling is one of the characteristics of breast cancer cells. Our preliminary findings have demonstrated antiproliferative effects of aloe emodin (AE), anthraquinone extract of *Aloe barbadensis Miller* on breast cancer cells, MCF-7. However, the influence of Ca^{2+} regulation in AE-treated breast cancer cells is not well known. Therefore, this study was done to discover the intracellular calcium dynamics of AE-suppressed proliferation in breast cancer cells, MCF-7. Cell viability after AE treatment for 1, 6 and 12 hours on MCF-7 cells were studied using trypan blue exclusion method. Intracellular calcium study was done by loading the MCF-7 cells with calcium specific fluorescent dye Fluo4-AM for 45 minutes and the fluo4 intensity changes over time were recorded using confocal laser scanning microscope. Fluorescence intensity was measured for untreated cells, Thapsigargin (TG) and AE treated cells. TG was used as positive control in this study as it is known to result in high cytosolic Ca^{2+} dynamics. Throughout cell viability determination, there is no significant cell death for all time points. However, AE treatment leads to a significant increase in cytoplasmic Ca^{2+} (mean \pm SD: 10.38 ± 1.02 ; $p < 0.05$) in comparison to untreated cells (5.55 ± 0.35). As expected TG treatment shows an expected increase in cytoplasmic Ca^{2+} intensity (25.39 ± 0.59 ; $p < 0.05$). These remarkable findings are crucial due to the facts that calcium is an important regulator of cell survival and apoptosis. An alteration in intracellular Ca^{2+} homeostasis ultimately leading to cell apoptosis and possibly is one of the pathways in AE-induced apoptosis in MCF-7 cells. Thus, our finding suggests that cytoplasmic Ca^{2+} regulation is involved in AE-suppressed proliferation of human breast cancer cells, MCF-7. Furthermore, this study provides valuable preliminary findings to further explore on the involvement of calcium signaling in the AE-breast cancer study.

CHAPTER 1

INTRODUCTION

1.1 Cancer

Cancer is defined by uncontrolled growth with the ability of the cells to spread to any other part of the body (Gabriel & Ebrary, 2007). Furthermore, characteristics of cancer cells include growth signals self-sufficiency, signal insensitivity for growth limitation, apoptotic evasion, unlimited replication, sustainability of angiogenesis and also ability to invade and metastasize (Hanahan & Weinberg, 2000). Cancer continues to be a major health issue of our time and contributes to the 10% of mortality worldwide and 25% in some countries (Pelengaris & Khan, 2006). According to Kreeger & Lauffenburger (2010), cancer is a disease that occurs as a consequence of the deregulation of various pathways governing basic cellular processes such as cell death, cell proliferation, differentiation, and also migration which alter the activities of molecular networks in a complex manner.

In addition, cancer can be classified as a heterogeneous disease which results from the cumulative defects of multiple genetic and also epigenetic and this later leads to deregulation in the cellular physiology such as cell signaling and as an ultimate outcome resulting in the impaired control of the cell division, motility, adhesion and also apoptosis (Hanahan & Weinberg, 2011).

In Malaysia, cancer is one of the most common causes of death. According to the National Cancer Registry 2007 done by the Ministry of Health of Malaysia, cancer is the third common cause of death in Ministry of Health Malaysia Hospitals after Heart Diseases of Pulmonary Circulation and Septicaemia (Zainal & Nor Saleha, 2011).
