## ABSTRACT

Hip arthritis often associated with total hip replacement (THR). It is estimated that by the year 2040, 78.4 million of adult aged 18 years and older in United State will suffering arthritis. As the population grows and ages increase; hence, the need of THR will increases. THR has become increasingly prevalent in relieving pain related to hip. Most of uncemented total hip replacement (THR) rely on press-fit for the initial stability and consequently lead to the secondary fixation namely biological fixation. The main key factor to a successful replacement is the implant stability. However, uncemented THR more prone to aseptic loosening as it the most reported cases in this surgery. Most of the patients will undergoes revision after 15 years utilizing the implant. Improper design and its material are among the aseptic loosening factors. The aim of this study is to propose a new material which having material properties closer to human cortical bone and develop a new hip prosthesis design to improve the fixation; hence, aseptic loosening can be minimized. In this present study, a new composite material which is Semantan (*Gigantochloa Scortechinii*) type of bamboo and glass fibre composite was introduced and subjected to a chemical treatment called epoxy coating prior to the fabrication of the composite as to increase the mechanical properties of the fibre. A three-dimensional model of hip prosthesis was then designed using CATIA V5 Software and analysed by using commercial Finite Element Software namely, ANSYS WORKBENCH V15 software to investigate the effect of using the new material properties and new chosen design of hip prosthesis in terms of mechanical stresses and deformation distribution. The new design of hip prosthesis has decreased the stress distribution and deformation occurred along the implanted femoral bone by 58% and 45% and the stiffness of new material of prosthesis was 88% closer to the femoral bone properties. Besides, the epoxy coating has increased the fibre-matrix adhesion. Therefore, the development of a new hip prosthesis design with Epoxy-coated/ treated EBEFEBE bamboo composite material was successfully reduced the mechanical stresses and deformation and consequently minimized the aseptic loosening.

## ACKNOWLEDGEMENT

In the name of Almighty Allah, The Most Beneficent, The Most Merciful.

Firstly, I wish to thank God for giving me the opportunity to embark on my PhD and for completing this long and challenging journey successfully. My gratitude and thanks go to my supervisor Assoc. Prof. Ts. Dr. Haji Solehuddin bin Shuib from Faculty of Mechanical Engineering who has given endless guide, support and inspiration throughout my postgraduate journey in Universiti Teknologi MARA (UiTM). Highly thanks to his unstoppable concerned and useful motivation during my study.

Moreover, I am also would like to thank my co-supervisor Dr. Ahmad Zafir bin Romli from Institute of Science who has help a lot on material aspect, giving support on running experimental work and testing in material laboratory. Unforgotten to my 2<sup>nd</sup> co-supervisor, Dr. Mohd Azman bin Yahya who have gave motivation on pursuing and completing my study. In addition, special thanks to Prof. Amran Ahmed Shokri, from School of Health, USM for the advices on Total Hip Replacement (THR) especially in my country, Malaysia.

My next appreciation goes to the Mr. Muhamad Faizal bin Abd. Halim who provided the facilities and assistance during sampling and conducting the experimental work in Institute of Science, UiTM Shah Alam, Selangor. Not to forget to other staff Mr. Mohd Rahimi bin Abdul Rahman and Mr. Mohd Harysham bin Zainal Abidin for their help and guide on using SEM and Alicona machine as well.

Special thanks and gratitude to my colleagues and friends for the moral support, inspiration and sharing knowledge throughout my journey.

Finally, this thesis is dedicated to the loving memory of my very dear late father, Hj. Ismail bin Md. Taib and my wonderful mother, Hjh. Rohana binti Abd. Majid for the vision and determination to educate me and also to my entire families. Besides, I am eternally grateful for the endless and countless support from my dear husband, Mr. Mohammad Husaini bin Mohamed Salleh. This piece of victory is dedicated to these special persons in my life.

# CHAPTER ONE

## INTRODUCTION

### 1.1 Research Background

Healthy bone allow humans to move around freely without any obstacles especially for the lower extremity part. An intact hip bone allows human a wide range of motion (RoM) in order to permits them to do normal daily activities such as walking, stair climbing, and also jumping as well. In general, the RoM of a typical hip joint during human daily activities consisted of internal-external rotation, abduction-adduction and also flexion-extension [1].

Figure 1.1 The Possible Hip Movement [2]

Activities like stair climbing and running may level up the transmission of forces to five times of the body weight (BW) while eight times for the condition of stumbling [3]. It is essential to have a healthy hip joint as it is the most crucial and important joint in anatomy of human. A normal human hip joint represented as ball and socket joint concept where the ball part is known as femoral head while the socket is the formation of the acetabulum. Besides, this hip joint is surrounded by a thin tissue which known as synovial membrane. This membrane will naturally lubricate the cartilage with a small amount fluid in a healthy hip joint; thus, it will knocked out almost all frictions that may present during its movement by decelerating the built-up heat on the surface of bearing and consequently avoid the area from damages [4][5].
